Multilevel, multivariate, and network meta-analysis with the *metafor* package in R

Wolfgang Viechtbauer Maastricht University The Netherlands

Purpose of Talk

- describe how multilevel and multivariate structures can arise in meta-analytic data
- illustrate how to fit multilevel, multivariate, and network meta-analyses with the metafor package in R

Meta-Analytic Data

- i = 1, ..., k studies
- have y_i and corresponding v_i
- assume:

$$y_i \mid \theta_i \sim N(\theta_i, v_i)$$

- and independence of the estimates (for now)
- approx. 95% CI for θ_i : $y_i \pm 1.96\sqrt{v_i}$

Example: BCG Vaccine

- effectiveness of the Bacillus Calmette-Guérin (BCG) vaccine against tuberculosis (TB)
- for each study, can compare the proportion of TB positive cases in the vaccinated versus the non-vaccinated group

Example: BCG Vaccine

	Tubero		
	Positive	Negative	
Vaccinated	4	119	123
Not Vaccinated	11	128	139

$$p_T = 4/123 = .0325$$

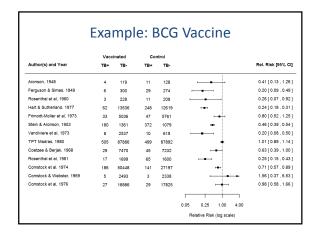

$$p_C = 11/139 = .0791$$

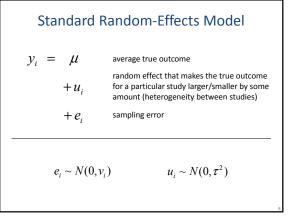

$$RR = \frac{4/123}{11/139} = .41$$

$$y = \ln[RR] = \ln\left[\frac{4/123}{11/139}\right] = -.89$$

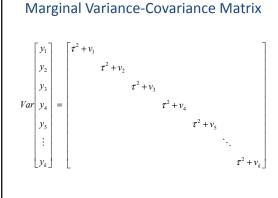

$$v = \frac{1}{4} - \frac{1}{123} + \frac{1}{11} - \frac{1}{139} = .326$$

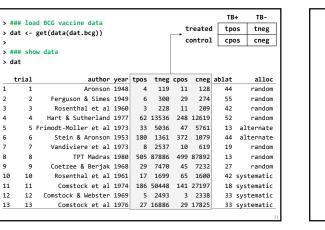

Example: BCG Vaccine RR y = ln(RR)Study Year Allocation Latitude 1948 0.41 -0.89 .326 random 44 1949 0.20 -1.59 .195 1960 -1.35 1977 0.24 -1.44 .020 1973 0.80 -0.22 .051 alternate 13 0.46 1953 -0.79 .007 alternate 0.20 -1.62 random 0.01 1968 0.63 -0.47 .056 random 27 0.25 -1.37 10 1961 .073 systematic -0.34 systematic 0.45 systematic 1976 0.98 -0.02 .071 systematic

Meta-Analysis with R

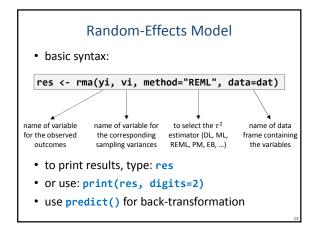

- metafor: meta-analysis package for R
- install with: install.packages("metafor")
- load with: library(metafor)
- · comments start with #

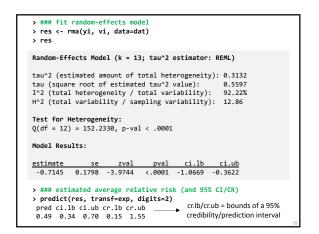

Computing Observed Outcomes

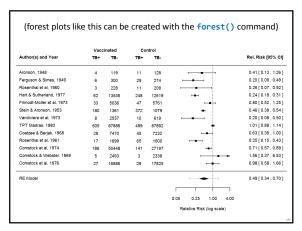

- can of course use external software for data management and preparations
- to compute outcomes: escalc() command
- · basic syntax:

Mixed-Effects Meta-Regression Model

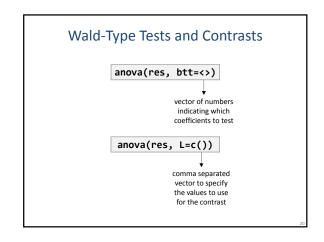

- can include moderators/predictors/covariates in the model (to account for heterogeneity)
- mixed-effects meta-regression model:
 - $y_i = \beta_0 + \beta_1 x_{i1} + \dots + \beta_p x_{ip} + u_i + e_i$
 - $u_i \sim N(0, \tau^2)$ (but now 'residual' heterogeneity)
 - $e_i \sim N(0, v_i)$

Mixed-Effects Meta-Regression Model

• basic syntax as before, but now:

```
res <- rma(yi, vi, mods = ~ var1, data=dat)
```

- for multiple predictors/moderators:
 - main effects: mods = ~ var1 + var2 + ...
 - interactions: mods = ~ var1 * var2 + ...
- · character/factor variables:
 - · are automatically dummy-coded
 - to remove the intercept: mods = ~ var1 1

```
> ### omnibus test of the 'alloc' factor
> anova(res, btt=2:3)

Test of Moderators (coefficient(s) 2,3):
QM(df = 2) = 1.2850, p-val = 0.5260

> ### test random versus systematic allocation
> anova(res, L=c(0,1,-1,0))

Hypothesis:
1: allocrandom - allocsystematic = 0

Results:
estimate se zval pval
1: -0.3260 0.3104 -1.0501 0.2937
```

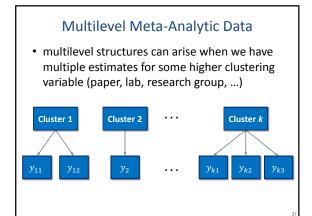

```
### load data

The rma.mv() Function

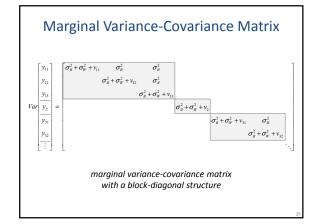

- more flexible model fitting function, but must specify random effects manually
- for now, replicate previous results

- random = ~ 1 | study adds a random effect for each level of the study variable
- method = "REML" is default (other option: ML)

```

The rma.mv() Function

- rma.mv() allows for the addition of multiple nested random effects
- random = ~ 1 | var1/var2 adds a random effect for each level of var1 and a random effect for each level of var2 within each level of var1

Correlation due to Multilevel Structure

• the multilevel structure implies that the true outcomes within a cluster are correlated:

$$\rho = \frac{\sigma_B^2}{\sigma_B^2 + \sigma_W^2}$$

• in example:

$$\hat{\rho} = \frac{0.0651}{0.0651 + 0.0327} = .67$$

• also note: 0.0651 + 0.0327 = 0.0978

Multivariate Parameterization

$$y_{ij} = \mu$$
 average true outcome
$$+ u_{ij} \qquad \begin{array}{c} \text{correlated random effects for the true} \\ \text{outcomes within the same cluster} \end{array}$$

$$+ e_{ij} \qquad \text{sampling error}$$

$$\begin{bmatrix} u_{i1} \\ u_{i2} \\ u_{i3} \end{bmatrix} \sim MVN \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \begin{bmatrix} \tau^2 & \rho \tau^2 & \rho \tau^2 \\ & \tau^2 & \rho \tau^2 \\ & & \tau^2 \end{bmatrix} \qquad e_{ij} \sim N(0, v_{ij})$$

Marginal Variance-Covariance Matrix

$$Var\begin{bmatrix} y_{11} \\ y_{12} \\ y_{13} \\ y_{2} \\ y_{31} \\ \vdots \end{bmatrix} = \begin{bmatrix} \tau^{2} + v_{11} & \rho \tau^{2} & \rho \tau^{2} \\ & \tau^{2} + v_{12} & \rho \tau^{2} \\ & & \tau^{2} + v_{13} \\ & & & & \\ & & & \\ &$$

The rma.mv() Function

- random = ~ var1 | var2 adds correlated random effects for each level of var1 within each level of var2
- note: var1 must be a character/factor type variable (if it is not, use factor() function)

Notes

- models assume independent sampling errors within clusters (sensible if no overlap in the data/subjects used to compute outcomes)
- examples:
 - multiple independent studies reported in paper
 - · multiple papers published by the same group
 - · results reported for different subgroups
- but true outcomes within clusters may be more similar to each other than those from different clusters (correlated true outcomes)

Multiple (Correlated) Outcomes • multivariate data also arise when multiple outcomes are measured within the studies Study 1 Study 2 Study k V11 V12 V21 V22 Note: not all studies have to measure all outcomes

Multiple (Correlated) Outcomes

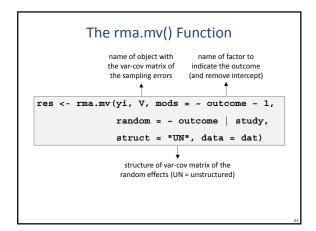

- since the outcomes are measured in the same subjects, the sampling errors are correlated
- true outcomes may also be correlated
- equations for the covariance between the sampling errors can be found in Gleser & Olkin (2009), Wei & Higgins (2013), Steiger (1980), ...

Multivariate Random-Effects Model

$$\begin{array}{ll} y_{ij} &=& \mu_j & \text{average true outcome for } j \text{th outcome} \\ &+ u_{ij} & \text{correlated random effects corresponding} \\ &+ e_{ij} & \text{correlated sampling errors of the observed} \\ &+ e_{ij} & \text{correlated sampling errors of the observed} \\ &\text{outcomes for the same study (with known var-cov matrix)} \end{array}$$

$$ar\begin{bmatrix} u_{i1} \\ u_{i2} \end{bmatrix} = \begin{bmatrix} \tau_1^2 & \rho \tau_1 \tau_2 \\ & \tau_2^2 \end{bmatrix} \qquad Var\begin{bmatrix} e_{i1} \\ e_{i2} \end{bmatrix} = \begin{bmatrix} v_{i1} & \cos v_i \\ & v_{i2} \end{bmatrix}$$

Multiple Time Points

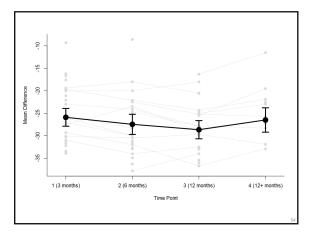

- multivariate data also arise when an outcome is measured at multiple time points
- the sampling errors will again be correlated
- · true outcomes may also be correlated
- can consider auto-regressive structures for the sampling errors and random effects (Ishak et al., 2007; Trikalinos & Olkin, 2012)

Random Effects Structures
$$\begin{aligned} & \text{struct="AR"} & \begin{bmatrix} \tau^2 & \rho \tau^2 & \rho^2 \tau^2 & \rho^3 \tau^2 \\ & \tau^2 & \rho \tau^2 & \rho^2 \tau^2 \\ & & \tau^2 & \rho \tau^2 \\ & & & \tau^2 \end{bmatrix} \\ & \text{struct="HAR"} & \begin{bmatrix} \tau_1^2 & \rho \tau_1 \tau_2 & \rho^2 \tau_1 \tau_3 & \rho^3 \tau_1 \tau_4 \\ & \tau_2^2 & \rho \tau_2 \tau_3 & \rho^2 \tau_2 \tau_4 \\ & & \tau_3^2 & \rho \tau_3 \tau_4 \\ & & & & \tau_4^2 \end{bmatrix} \end{aligned}$$

Network Meta-Analysis

- often there are multiple treatments available for the same condition/disease
- studies comparing the effectiveness of these treatments form a network of comparisons
- · some of the goals:
 - synthesize evidence provided by all studies and comparisons in one parsimonious model
 - obtain indirect evidence about comparisons that have not been examined head-to-head
 - · determine a hierarchy of treatment effectiveness

Star-Shaped Networks Second-generation antiepileptic drugs in partial epilepsy a: levetiracetam, b: gabapentin, c: lamotrigine, d: oxcarbazepine, e: tiagabine, f: topiramate, g: zonisamide, h: placebo

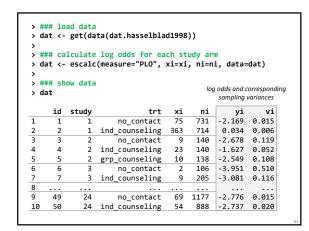

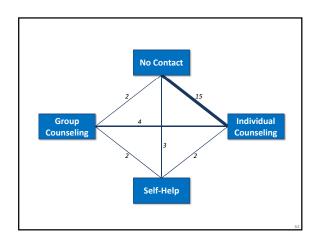

Network Meta-Analysis

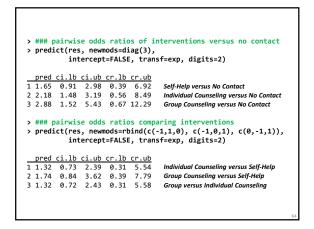

- can analyze such data with appropriate multilevel/multivariate models
- two general approaches: arm- vs. contrastbased model (e.g., Salanti et al., 2008)
- errors are correlated in contrast-based model for studies with more than two groups
- equations for the correlation between the sampling errors can be found in Gleser and Olkin (2009) and several other papers

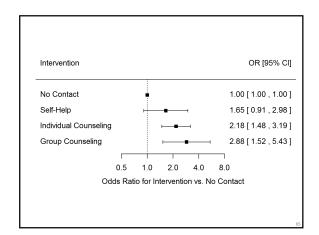

Arm-Based Network Meta-Analysis

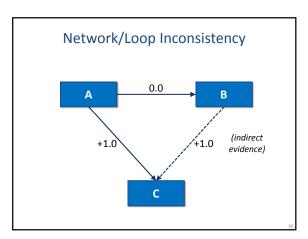

$$y_{ij} = \beta_0 + \beta_1 T_{i1} + \ldots + \beta_p T_{ip} \qquad \text{$(T_{ij}$ = treatment indicators)} \\ + w_i \qquad \qquad \text{random effect that makes the true outcomes for a particular study larger/smaller by some amount (between-study heterogeneity)} \\ + u_{ij} \qquad \qquad \text{random effect that makes one of the true outcomes within a particular study larger/smaller by some amount (between-treatment heterogeneity)} \\ + e_{ij} \qquad \qquad \text{sampling error} \\ \\ w_i \sim N(0, \sigma_S^2) \qquad u_{ij} \sim N(0, \sigma_T^2) \qquad e_{ij} \sim N(0, v_{ij})$$

Network/Loop Inconsistency 0.0 R (direct -0.5 +1.0 evidence)

Dealing with Inconsistency

- restrict analysis to a subset of studies providing consistent evidence
- try to account for it based moderators
- model it (various proposals)

Final Notes

- rma.mv() allows for an arbitrary number of random effects of the form ~ 1 | factor (allows for 3/4/...-level models and crossed random effects)
- up to 2 terms of the form ~ inner | outer
- can also specify a known correlation matrix corresponding to a ~ 1 | factor term (e.g., for phylogenetic meta-analyses)
